

# AxSTREAM SYSTEM SIMULATION

## Modeling a 500 MW Steam Turbine Lubrication System

### Case Study Summary

#### Goals:

Select equipment which will provide the necessary mass flow rate and oil cooling requirements. Accurately design an oil supply pipeline system in AxSTREAM System Simulation

#### Requirements:

Determine the oil flow rate for thrust, the journal bearings oil supply, and the oil cooling behaviours.

#### Parameters:

HPC bearings - 300x170 mm  
 IPC bearings - 420x220 mm  
 LPC bearings - 520x270 mm  
 HEX heat transfer area - 193.6 m<sup>2</sup>  
 Number of tubes - 1296  
 Outlet tube diameter - 16x1 mm  
 Length of tube - 2960 mm

#### Constraints:

P<sub>water</sub> = 200 kPa  
 T<sub>water</sub> = 33 °C

#### Results:

By successfully accounting for the pump characteristics and the oil cooler/bearing properties, an accurate model was built, and the subsequent analysis was completed in as little as 2 minutes. The temperature drops at the heat exchangers and the hydraulic resistance of the system were estimated quickly, allowing for additional analyses and iterations.

### Hydraulic Network and Oil Cooler

The lubrication system was built in AxSTREAM System Simulation based on known basic geometric and operating data, including oil cooler properties and material properties.

Oil pump characteristics were specified and added in through a table to simulate off-design conditions for the whole system.

Pump characteristic curves

➤ Table for dependency of normalized **head** from flow rate

Q	50	100	150	200	250	290	300	350	400	
Head	1.2677484	1.2550709	1.2373225	1.1942190	1.1359026	1.0649087	1	0.9837728	0.8924949	0.8037525

Interpolation: Linear      Extrapolation: Linear

➤ Table for dependency of **efficiency** from flow rate

Q	50	100	150	200	250	290	300	350	400	
Efficiency	0	0.25	0.45	0.6	0.7	0.74	0.796	0.76	0.75	0.705

Interpolation: Linear      Extrapolation: Piecewise constant

In addition to using the component library which was done in this study, the user can set up their own scripted methods for completing calculations.

#### Bearing calculation by **Codnir method** in C# script

Advantage: Flexibility to model any component through scripting

#### Input data:

- Bearing length, mm
- Bearing diameter, mm
- Rotational speed, rpm
- Load, N
- Bearing radial clearance, mm

#### Calculation results:

- Oil consumption for bearing, m<sup>3</sup>/s
- Outlet oil temperature, °C

```

// Input data
double L = 520; // Bearing length [mm]
double D = 520; // Bearing diameter [mm]
double n = 3000; // Rotational speed [rpm]
double F = 90000; // Load [N]
double rc = 0.25; // Bearing radial clearance [mm]

// Calculation
double Q_oil = 0.00184; // Oil consumption [m³/s]
double T_oil = 85.83; // Outlet oil temperature [°C]

// Output
Console.WriteLine("Oil consumption: " + Q_oil + " m³/s");
Console.WriteLine("Outlet oil temperature: " + T_oil + " °C");
    
```
